Abstract

1 Graphic modeling remains a grueling task in the field of 3D animations. Having a
2 program that understands natural language to deduce the expected action by the
3 designer would pave the way to removing the skill barriers required to enter the
4 field. To address this problem we propose to create a method which will be able to
5 generate animations from any natural text describing an action through code.

6 1 Introduction

7 In the world of 3D animation, animators spend a laborious amount of time designing characters and
8 minute details. Having an automated way of Generating 3D Animations would lower the barrier
9 to entering the field and increase the efficiency of those experienced in the field. Creating Models
10 which will be able to render code directly from text to 3d animation would help achieve a deeper
11 understanding between natural language context and their meaning in the real world. There also exists
12 Graphic animation software like Unreal Engine[3], in which we can use code to render objects to
13 animate them. With the onset of large language models like the Codex[1], which can directly generate
14 code, we can expedite the process of generating animations. This way, animators will be able to use
15 natural language to generate 3D animations. This would increase the efficiency of 3D animation as
16 the animator would no longer need to manually code each part of the animation they want to create.
17 Instead, they could give the language model a context and the model would generate the code to
18 create the desired animation. This will also help to bridge the gap between natural language and the
19 representation of the physical world. By having a model that is able to generate code from natural
20 language, animators will be able to create animations that accurately represent the context given. This
21 could be used to animate characters, objects and scenes in a much more efficient and accurate way.
22 In this project, we try to achieve this on CARLA[2], which is an open-source simulator for autonomous
23 driving research. We use a language model to generate code from natural language context, which
24 renders and animates objects in the simulation.
25 In conclusion, the use of automated 3D animation generation will help to reduce the amount of time
26 and effort required to create 3D animations. This will help animators to create more accurate and
27 efficient animations in a much shorter amount of time. It will also help bridge the gap between natural
28 language and the physical world, as the language model will be able to generate code from natural
29 language context. This could be used to create animations of characters, objects, and scenes in a
30 much more efficient and accurate way.

31 2 Related Work

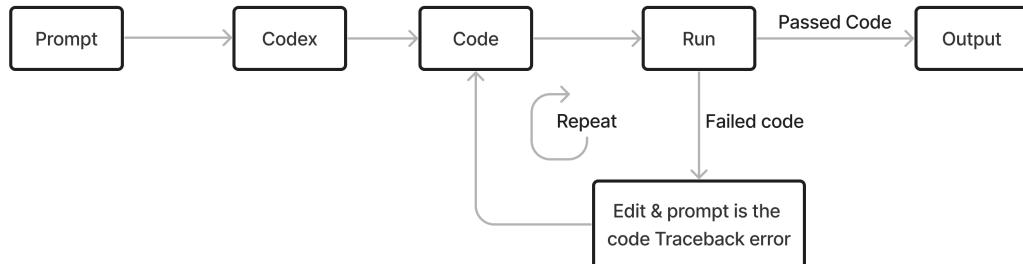

32 Previous work in the field of text-to-3D animation has focused on primarily human centered ani-
33 mations. For example, the work by Hong et. al.[4][6] takes CLIP images generated using text and
34 trains their model to generate 3D animations, but it is only able to generate human-like subjects in
35 their animations. Similarly work by Zhang et. al.[10], a text driven human motion generation with
36 diffusion model which demonstrates several desired properties over existing models. Previous work

37 in the field of text to Code[8],[5] are created to solve the problem to generate code from text, but is
 38 not trained specifically to solve problems related to computer graphics.
 39 None of the works mentioned above have been applied to the field of graphic generation. This project
 40 is the first to apply text-to-code to the field of 3D animation generation. We use a language model to
 41 generate code from natural language context, which renders and animates objects in the simulation.
 42 The results of this project demonstrate that it is possible to generate 3D animations from natural
 43 language context. We were able to generate animations of cars and other objects in the CARLA
 44 simulator. The results of this project show that it is possible to generate 3D animations from natural
 45 language context, which can be used to create more accurate and efficient animations. This could be
 46 used to animate characters, objects and scenes in a much more efficient and accurate way.

47 3 Methodology

48 We have developed two modes for producing code given a prompt. The generation mode is used to
 49 create a code from scratch and The edit mode is useful when the user wants to modify the existing
 50 code to make it more efficient or to add new features. The user can provide the instruction to the
 51 Codex api and it will generate the modified code. The generated/modified code is then run locally to
 52 check for errors. If errors are present, the code is regenerated using the traceback error as prompt.
 53 This process is repeated until the code is error-free.

Code Generation

Edit Existing Code

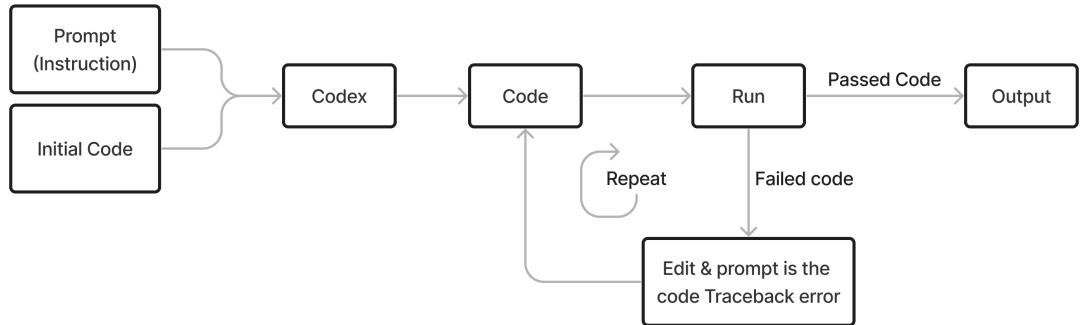

Figure 1: Flow diagram of methodology implemented

54 **4 Results**

55 **4.1 Identifying limitations and strength of Codex**

56 We first wanted to understand limitations of current state-of-the-art image generation model when
57 compared to code generation using Codex. We came up with 10 adversarial examples which are
58 performed poorly by DALL.E[7] but Codex is able to generate accurately in Opensource framework
59 for python OpenGl[9](Fig:2).

60 **4.1.1 Observations from this exercise**

- 61 1. Codex fails to generate the desired model or creates a default mode of cube if the prompt is
62 not in detail or complex
- 63 2. Sometimes Codex generates incomplete/incorrect code in the first iteration, reiterating again
64 for couple of times gives the desired output
- 65 3. Codex started generating better models as we give more detail in the prompt.
- 66 4. Codex runs into infinite loop for some prompts

67 **4.2 Rendering using prompts on CARLA**

68 We were able to render and modify properties of objects in CARLA. As an example we were able to
69 change color of all cars in CARLA to blue (fig:3).

70 Github repo: https://github.com/97harsh/graphic_codex

71 **5 Limitations**

- 72 1. Codex
 - 73 (a) The code generated by the Codex may be inaccurate and not able to completely do
74 what the prompt expects it to do.
 - 75 (b) The code may undo or comment out the modifications it made in order to rectify any
76 errors.
 - 77 (c) Codex attempts to render objects that are not available in CARLA.
- 78 2. CARLA
 - 79 (a) The current version of CARLA has inconsistencies in the attributes for similar objects.
